DESCRIPTION

CHEMICALLY-MODIFIED G-CSF

Technical Field

The present invention relates to a chemical modification of granulocyte colony-stimulating factor (G-CSF), by which chemical and/or physiological properties of G-CSF can be changed.

Background Art

Human G-CSF is one of haematopoietic growth factors. It has been shown to be present in the conditioned medium of a human bladder carcinoma cell line denominated 5637 (ATCC HT8-9) (Welte et al., Proc. Natl. Acad. Sci. (USA), 82, pp.1526-1530, (1985)). The determination of a DNA sequence encoding human G-CSF (Japanese Patent Application Laying Open KOHYO No. 500636/88) has enabled the production of human G-CSF by means of recombinant genetic techniques.

Human G-CSF may be useful in the treatment of general haematopoietic disorders including those arising from chemotherapy or from radiation therapy. It may be also useful in bone marrow transplantation. Wound healing burn treatment and the treatment of bacterial inflammation may also benefit from the application of human G-CSF (Welte et al., supra.).

It is generally observed that physiologically-active proteins administered into body can show their pharmacological activity only for a short period of time due to their high clearanc rate in body. Furthermore, high

hydrophobicity of the proteins would reduce their stability.

For the purpose of decreasing the clearance rate, improving in stability or abolishing antigenicity of the proteins, some methods have been proposed wherein the proteins are chemically modified by using polyethylene glycol. Japanese Patent Application Laying Open KOHYO No. 289522/87, for EXAMPLE, discloses the reduction in immunogenicity of TNF which has been modified by polyethylene glycol. Japanese Patent Application Laying Open KOHYO No. 503171/87 discloses with respect to IL-2 and IFN-β the reduction in immunogenicity and aggregating property in an aqueous solution, and the prolongation of half-life in blood. In addition, there are disclosed the prolongation of half-life in blood and the disappearance of antigenicity or immunogenicity owing to the modification by polyethylene glycol with respect to a plasminogen activator (Japanese Patent Application Laying Open KOHYO No.60938/88), IL-2, IFN-γ and SOD (Japanese Patent Application Laying Open KOHYO No.10800/88), and IAP (Japanese Patent Application Laying Open KOHYO No.126900/88).

However, these prior arts have not disclosed an improvement in biological activity and pharmacokinetics, which may be expected as a result of the modification of human G-CSF by polyethylene glycol.

Accordingly, it has been desired to prolong the half-life of human G-CSF in body so as to enhanc its

lasting effect, as may be expect d. Furthermore, G-CSF
which may accelerate to recover from neutropenia sooner has
been desired.

Disclosure of Invention

 After vigorous investigations in order to solve
the above problems, the present inventors have now found
that the above desire can be realized by binding
polyethylene glycol to human G-CSF, and have completed the
present invention..

 Any purified and isolated human G-CSF which is
produced by host cells such as E. coli and animal cells
transformed by using recombinant genetic techniques may be
used in the present invention.

 Among them, the human G-CSF which is produced by
the transformed E. coli is particularly preferable. Such
human G-CSF may be obtained in large quantities with high
purity and homogeneity and substantially has the following
amino acid sequence:

(Met)n

Thr Pro Leu Gly Pro Ala Ser Ser Leu Pro Gln

Ser Phe Leu Leu Lys Cys Leu Glu Gln Val Arg

Lys Ile Gln Gly Asp Gly Ala Ala Leu Gln Glu

Lys Leu Cys Ala Thr Tyr Lys Leu Cys His Pro

(n=0 or 1)

The above human G-CSF may, for example, be prepared according to a method disclosed in Japanese Patent Application Laying Open KOHYO No.500636/85. The wordings "substantially has the following amino acid sequence" mean that the above amino acid sequence may include one or more amino-acid changes (deletion, addition, insertion or replacement) as long as such changes will not cause any disadvantageous non-similarity in function to a naturally-occurring human G-CSF.

It is more preferable to use the human G-CSF substantially having the above amino acid sequence, in which at least one lysine, aspartic acid or glutamic acid residue is included.

According to the present invention, polyethylene glycol is covalently bound through amino acid residues of the polypeptide of human G-CSF. The amino acid residue may be any reactive one having, for example, free amino or carboxyl groups, to which a terminal reactive group of an activated polyethylene glycol may be bound. The amino acid residues having the free amino groups may include lysine residues and N-terminal amino acid residue, and those having the free carboxyl group may include aspartic acid, glutamic acid residues and C-terminal amino acid residue.

A molecular weight of the polyethylene glycol used in the present invention is not restricted to any particular range, being, however, normally of from 500 - 20,000 and preferably of from 4,000 - 10,000.

Polyethylene glycol is bound onto human G-CSF via its terminal reactive group (or "a spacer"). Polyethylene glycol having the spacer is hereinafter referred to as "an activated polyethylene glycol". The spacer, for example, is that which mediates a bond between the free amino or carboxyl groups and polyethylene glycol. The activated polyethylene glycol which may be bound to the free amino group includes N-hydroxysuccinylimide polyethylene glycote having the following formula:

$$CH_3O(C_2H_4O)_nCOCH_2CH_2COON < \begin{matrix} \overset{O}{\overset{\|}{C}} \\ \\ \underset{O}{\underset{\|}{C}} \end{matrix} |$$
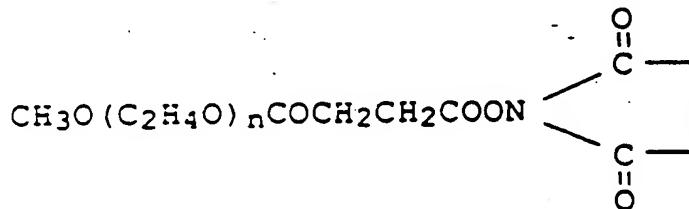

which may be prepared by activating succinic acid ester of polyethylene glycol with N-hydroxysuccinylimide. Another activated polyethylene glycol which may be bound to free amino group is 2,4-bis(O-methoxypolyethyleneglycol)-6-chloro-s-triazine having the following formula:
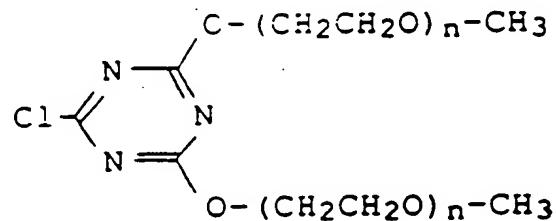

$$Cl \underset{N}{\overset{N}{<}} \underset{=}{\overset{}{}} \underset{N}{} \begin{matrix} C-(CH_2CH_2O)_n-CH_3 \\ \\ O-(CH_2CH_2O)_n-CH_3 \end{matrix}$$

which had been prepared by reacting polyethylene glycol monomethyl ether with cyanuric chloride. The activated polyethylene glycol which is bound to the free carboxyl

group includes polyoxyethylenediamine having the following formula:

$$H_2NCH_2CH_2CH_2O(C_2H_4O)_nCH_2CH_2CH_2NH_2$$
The chemical modification through a covalent bond may be performed under any suitable condition generally adopted in a reaction of a biologically active substance with the activated polyethylene glycol. In case where the reactive amino acid residues in human G-CSF have the free amino groups, the above modification is preferably carried out in a buffer solution such as phosphate and borate (pH 7.5 - 10.0) for 1 - 5 hrs at 4 - 37°C. The activated polyethylene glycol may be used in 1 - 200 times, preferably 5 - 50 times the molar amount of the number of free amino groups of human G-CSF. On the other hand, in case where the reactive amino acid residues in human G-CSF have the free carboxyl groups, the above modification is preferably carried out in pH 3.5 - 5.5, for example, the modification with polyoxyethylenediamine is carried out in the presence of carbodiimide (pH 4.0 - 5.0) for 1 - 24 hrs at 4 - 37°C. The activated polyethylene glycol may be used in 1 - 200 times the molar amount of the number of free carboxyl groups of human G-CSF.

The extent of the modification of the amino acid residues may be optionally controlled depending on an amount of the activated polyethylene glycol used in the modification.

A polyethylene glycol-modified human G-CSF, namely chemically modified protein according to the present invention, may be purified from a reaction mixture by conventional methods which are used for purification of proteins, such as dialysis, salting-out, ultrafiltration, ion-exchange chromatography, gel chromatography and electrophoresis. Ion-exchange chromatography is particularly effective in removing unreacted polyethylene glycol and human G-CSF.

The present polyethylene glycol-modified human G-CSF has lasted its pharmacological effect, which may be possibly attributed to its prolonged half-life in body.

Furthermore, it is observed that the present polyethylene glycol-modified human G-CSF may accelerate the recovery from neutropenia.

The present polyethylene glycol-modified human G-CSF has essentially the same biological activity as an intact human G-CSF and may accordingly be used in the same application as that. The polyethylene glycol-modified human G-CSF has an activity for increasing the number of neutrophils, and it is therefore useful in the treatment of general haematopoietic disorders including those arising from chemotherapy or from radiation therapy. It may be also useful in the treatment of infection and under receiving the therapy of bone marrow transplantation.

The present polyethylene glycol-modified human G-CSF may be formulated into pharmaceuticals containing also a pharmaceutically acceptable diluent, an agent for

preparing an isotonic solution, a pH-conditioner and the like in order to administer them into a patient.

The above pharmaceuticals may be administered subcutaneously, intramuscularly, intravenously or orally, depending on a purpose of treatment. A dose may be also changed on a kind and condition of the disorder of a patient to be treated, being normally between 0.1 μg and 5 mg by injection and between 0.1 mg and 5 g in an oral administration for an adult .

Brief Description of Drawings

FIG.1 shows scanning patterns of PEG (4,500) G-CSF obtained by SDS-PAGE. The molar ratio of the activated PEG to the free amino groups of the human G-CSF is 0 for (a), 1 for (b), 5 for (c), 10 for (d) and 50 for (e), respectively. The peak of the intact human G-CSF is marked with *.

FIG.2 shows the time course of the change in number of neutrophils in mice after administration with human G-CSF or PEG-modified G-CSF. Each point represent an average value obtained from six mice with a standard deviation.

FIG.3 shows an accelerating effect of PEG-modified human G-CSF on the recovery from neutropenia induced by cyclophosphamide. Each point represents an average value obtained from six mice with a standard deviation.

FIG.4 shows an accelerating effect of PEG-modified G-CSF on the recovery from neutropenia induced by

5-FU. Each point represents an average value obtained from six mice with a standard deviation.

FIG.5 shows the results obtained in the study of half-life in serum of PEG (10,000) G-CSF (O) and human G-CSF (●). Each point represents an average value from three rats with a standard deviation.

Best Mode for Carrying Out the Invention

The present invention will be further illustrated by referring to the following EXAMPLEs which, however, are not be construed as limiting the scope of the present invention.

EXAMPLE 1

Preparation of PEG (4,500) G-CSF

Recombinant human G-CSF (Japanese Patent Application Laying Open KOHYO No. 500636/88) having the following amino acid sequence was used for the chemical modification according to the present invention:

Met

As the activated polyethylene glycol (PEG) was used Methoxypolyethyleneglycol-Succinimydyl Succinate (Nippon Oil and Fats, Co., Ltd.) which had been prepared by activating a succinic acid ester of polyethylene glycol with an average molecular weight of about 4,500 with N-hydroxysuccinylimide.

The human G-CSF was incubated in 0.25 M sodium borate buffer (pH 8.0) for 1 hr at 4°C with the activated PEG in 1 - 50 times the molar amount of the number of the free amino groups in the human G-CSF. The resulting product was applied to Sephadex G25 which had been equilibrated with 10 mM NH4HCO3 for buffer-exchange, and then to DEAE ion-exchange chromatography so as to separate the PEG-modified human G-CSF from the agent and, if necessary, an unreacted human G-CSF. The resultant PEG-modified human G-CSF is hereinafter referred to as "PEG (4,500) G-CSF".

EXAMPLE 2

Characterization of PEG (4,500) G-CSF

PEG (4,500) G-CSF prepared in EXAMPLE 1 was characterized by the number of unmodified amino groups and a molecular weight estimated by SDS-PAGE.

The number of the unmodified amino groups was determined by reacting them with 0.1% TNBS in 4% NaHCO3 followed by measurement of absorbance at 335 nm (Habeeb et al., Anal. Biochem., 14, pp.328-336, (1966)).

The molecular weight of PEG (4,500) G-CSF was determined by SDS-PAGE (16% gel, CBB staining) according to a method of Laemli, Nature, 227, p.680, 1970. Each lane on

the gel was scanned by using a chromato-scanner (SHIMADZU CORPORATION: CS-930) after staining.

When a molar ratio of the activated PEG to the number of free amino groups of human G-CSF increased, the extent of the modification also increased. The product prepared in said molar ratio of 1 has in addition to a band corresponding to an intact human G-CSF (19 K) another band with an apparent molecular weight of about 26 K (FIG. 1). With respect to the product prepared in the molar ratio of 5 or more, a band with a higher molecular weight was observed besides the above two bands. By scanning the resulting gel, a content of each band was determined. From the result in TABLE 1, it is estimated that the band of 26 K consists of human G-CSF wherein one human G-CSF molecule is bound with one activated PEG molecule and that a band of 34 K consists of human G-SCF wherein one human G-CSF molecule is bound with two activated PEG molecules.

TABLE 1 Characterization of PEG (4,500) G-CSF

| PEG/NH$_2$	Distribution			Modified NH$_2$ (%)	Unmodified NH$_2$ (an average number)
	19K	26K	34K		
1	86	12		5	4.8
2	68	31	1	15	4.3
3	56	42	2	15	4.3
4	36	48	16	20	4.0
5	31	49	20	27	3.7
6	25	50	25	27	3.7
7	20	50	28	27	3.7

It was found that based on patterns obtained by SDS-PAGE of the fractions from the ion-exchange chromatography (shown in FIG.1) that the human G-CSF with a higher modification extent was eluted faster from a column and that the fraction finally eluted therefrom contained the intact human G-CSF.

The scanning patterns by SDS-PAGE of PEG (4,500) G-CSFs including those obtained with a higher molar ratio of PEG/NH_2 are shown in FIG.1.

EXAMPLE 3

Preparation of PEG (10,000) G-CSF

The same human G-CSF as used in EXAMPLE 1 was modified by an activated polyethylene glycol (an activated PEG 2; Seikagaku Kogyo K.K.) with a molecular weight of about 10,000 having the following formula:
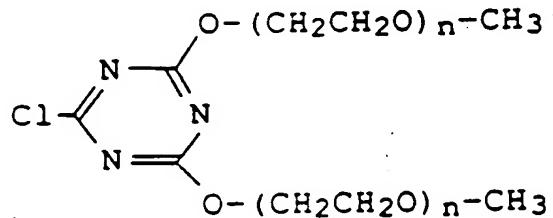

$$Cl-\underset{\underset{N}{\overset{N}{\bigg|}}}{\overset{N}{\bigg\langle}}\underset{N}{\overset{O-(CH_2CH_2O)_n-CH_3}{\diagdown}}$$
$$O-(CH_2CH_2O)_n-CH_3$$

which had been prepared by reacting polyethylene glycol monomethyl ether with cyanuric chloride.

The human G-CSF was incubated with the activated PEG 2 of 5 times of the molar of the number of the free amino groups of the human G-CSF in 0.25 M sodium borate buffer solution (pH 10.0) for 1 hr at room temperature. The resulting product was applied to Sephadex G25 which had been equilibrated with 10 mM NH_4HCO_3 for buffer- xchange,

and then to DEAE ion-exchange chromatography to separate
the PEG-modified human G-CSF from an unreacted human G-CSF
and reagent. The estimation of a molecular weight of the
product by SDS-PAGE as in EXAMPLE 2 has revealed that its
average molecular weight is about 45 K with distributed
among 30 K (10%), 40 K (70%) and 66 K (20%). The resultant
PEG-modified human G-CSF is hereinafter referred to as "PEG
(10,000) G-CSF".

Moreover, the human G-CSF was incubated with the
activated PEG 2 of 10 times of the molar of the number of
free amino groups of the human G-CSF in 0.25 M sodium
borate buffer solution (pH 10.0) for 2 hrs at room
temperature. The resulting product was subjected to
separation in the same manner as stated above.

It is estimated in the same manner as in EXAMPLE 2
that the product of 30 K consists of human G-CSF wherein
one human G-CSF molecule is coupled with one activated PEG
molecule.

Furthermore, the human G-CSF was incubated with
the activated PEG 2 of 50 times of the molar amount of the
number of free amino groups of the human G-CSF.

The estimation of a molecular weight of the
resulting products by SDS-PAGE as in EXAMPLE 2 has revealed
that its average molecular weight is about 51 K with
distributed among 40 K (58 %) and 66 K (42 %).

EXAMPLE 4

Preparation of PEG (4,000) G-CSF

PEG-modified human G-CSF was prepared by covalently binding an activated polyethylene glycol, or polyoxyethylenediamine with an average molecular weight of 4,000 (Nippon Oil and Fats Co., Ltd.) to the above human G-CSF through the free carboxyl group thereof.

The human G-CSF and the activated polyethylene glycol of 60 times of the molar of the number of the free carboxyl groups of the human G-CSF were incubated in the presence of 0.05 M 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide at a room temperature for overnight. The reaction was terminated by adding 1 M sodium acetate (pH 4.75) and further incubated at 25°C in the presence of 0.5 M hydroxyamine for 5 hrs in order to regenerate tyrosine residues. The resulting product was subjected to gel chromatography on TSK G3000SW which had been equilibrated with 10 mM sodium acetate (pH 5.5) to separate the PEG-modified human G-CSF from an unreacted human G-CSF and reagent. The estimation of a molecular weight of the product by SDS-PAGE as in EXAMPLE 2 has revealed that its molecular weight is distributed among 27 K (70%), 35 K (20%) and 42 K (10%). The resultant PEG-modified human G-CSF is hereinafter referred to as "PEG (4,000) G-CSF".

EXAMPLE 5

In vivo biological assay of PEG (4,500) G-CSF

Male ICR mice (Experiment I: 4 weeks old, Experiment II: 8 weeks old) were used for *in vivo* assays for pharmacological activity of PEG (4,500) G-CSF obtained

in **EXAMPLE** 1. Samples of the intact human G-CSF and PEG
(4,500) G-CSF were intravenously injected into mice at a
dose of 10 μg or 100 μg protein/kg. At 24 hrs (10 μg
protein/kg) or 32 hrs (100 μg protein/kg) after the
injection, blood was collected from orbital vein and
leukocytes were counted by an auto blood cell counter E-
2000 (Toa Medical Electronics, Japan). At the same time,
blood smear was subjected to Wright-Giemsa stain and
leukocytes fraction was determined by an auto blood cell
analyzer MICROX (OMRON TATEISI ELECTRONICS CO.) to count
the number of neutrophils. The results are summarized in
TABLE 2 below.

In TABLE 2, PEG (4,500) G-CSF (1) is a product
obtained in the reaction wherein the molar ratio of the
activated PEG / the free amino group was five (FIG.1, C),
PEG (4,500) G-CSF (2) is a 26 K fraction obtained from DEAE
ion-exchange chromatography, and PEG (4,500) G-CSF (3) is a
high molecular fraction (26 K:14%, 34 K:55%, >34 K:28%)
obtained from said DEAE ion-exchange chromatography.

From the above results, it is observed that the
number of neutrophils in the mice injected with PEG (4,500)
G-CSFs (1), (2) and (3) have been much more increased than
those in the mice injected with the intact G-CSF.
Especially, PEG (4,500) G-CSFs (1) and (3) with a higher
extent of the modification showed a remarkable increase in
the number of neutrophils.

When human G-CSF is injected into mice at a dose
of 10 μg protein/kg, the number of neutrophils increases,

and generally at 6 - 12 hrs after the injection, it gets to
the maximum. After that, the number of neutrophils
decreases slowly to a basal level about 30 hrs after
injection. When 10 μg protein/kg injection, 24 hrs
corresponds to the time span as normally required for the
number of neutrophils which has once increased to again
decrease almost to a basal level. In the case of 100 μg
protein/kg injection, based on the above, the time for
collection of blood (32 hrs after the injection) was
determined. Accordingly, the above result that the numbers
of neutrophils in the mice injected with PEG (4,500) G-CSFs
(1), (2) and (3) are higher than those in the mice injected
with the intact hG-CSF may indicate that the activity of
human G-CSF in mice has been lasted by the present
modification.

A mixture of human G-CSF and PEG did only show
the same result as the intact human G-CSF (Data are not
shown).

TABLE 2 Pharmacological activity (in vivo) of PEG-modified human G-CSF

Group		N	neutrophils ($\times 10^2 / \mu$ l)	Ratio (to vehicle)
a. 10 μ g/kg				
< Exp. I >				
vehicle		5	5.6±1.0	1.0
control	G-CSF	6	9.6±1.4	1.7
PEG(4500)	G-CSF(1)	6	20.8±2.6	3.7
PEG(4500)	G-CSF(2)	6	17.5±3.0	3.1
< Exp. II >				
vehicle		6	12.3±1.7	1.0
control	G-CSF	6	27.1±4.6	2.2
PEG(4500)	G-CSF(3)	6	54.0±7.2	4.4
b. 100 μ g/kg				
< Exp. I >				
vehicle		6	6.6±0.7	1.0
control	G-CSF	6	18.5±2.3	2.8
PEG(4500)	G-CSF(1)	6	42.9±4.3	6.5
PEG(4500)	G-CSF(2)	6	22.6±1.9	3.4

EXAMPLE 6

In vivo biological assay of PEG (4,000) G-CSF

Male ICR mice (7 weeks old) were used for *in vivo* assays for pharmacological activity of PEG (4,000) G-CSF obtained in EXAMPLE 4. Samples of the intact human G-CSF and PEG (4,000) G-CSF were intravenously injected into mice at a dose of 10 μg protein/kg. At 24 hrs after the injection, blood was collected from orbital vein and the number of neutrophils was counted as in EXAMPLE 5. The results are shown in TABLE 3.

It has been revealed that PEG (4,000) G-CSF in which the activated PEG is bound through the free carboxyl group has also increased the number of neutrophils more than the intact human G-CSF has.

TABLE 3 Pharmacological activity (in vivo) of PEG (4,000) G-CSF

Group	Number of Animals	Number of Neutrophils $(\times 10^2 / \mu l)$	Ratio (to vehicle)
Vehicle	6	10.9 + 1.0	1.0
G-CSF (control)	6	16.4 + 1.4	1.5
PEG (4,000) G-CSF	6	23.3 + 2.5	2.1

EXAMPLE 7

Increasing Effects of PEG-modified human G-CSFs on mice neutrophils

Male ICR mice (7 weeks old) were used for in
vivo assays, for pharmacological activity of PEG (4,500) G-
CSF and PEG (10,000) G-CSF obtained in EXAMPLEs 1 and 3,
respectively. PEG (4,500) G-CSF used here is a high
molecular fraction from DEAE ion-exchange chromatography of
a product obtained in the reaction wherein the molar ratio
of the activated PEG / the free amino group was fifty (an
average molecular weight of 60K; 38K:20%, 58K:54%,
80K:27%). Samples of the human G-CSF, PEG (4,500) G-CSF
and PEG (10,000) G-CSF were intravenously injected into
mice at a dose of 10 μg protein/kg. At 6, 24, 32, 48 and
72 hrs after the injection, blood was collected from
orbital vein and the number of neutrophils was counted as
in EXAMPLE 5, except for using an auto blood cell counter
CC180-A (Toa Medical Electronics, Japan).

As shown in FIG.2, in the case of the intact
human G-CSF, the number of neutrophils decreases to a basal
level 24 hrs after the injection. On the other hand, a
significant increase of neutrophils was observed over 32
hrs and 48 hrs after the injection for PEG (4,500) G-CSF
and PEG (10,000) G-CSF, respectively.

Moreover, male ICR mice (8 weeks old) were
intravenously administered with the PEG (10,000) G-CSFs
obtained in EXAMPLE 3; (a) an average molecular weight of
30 K, (b) an average molecular weight of 51 K; 40K:58%,
66K:42% at a dose of 10 μg protein/kg. At 24 hours after
the injection the number of neutrophils was counted as in
EXAMPLE 5. The results are shown in TABLE 4.

TABLE 4 Pharmacological activity (in vivo) of PEG (10,000) G-CSF

Group	Number of Animals	Number of Neutrophils (x 10^2 / µl)	Ratio (to vehicle)
Vehicle	5	7.4 + 0.6	1.0
G-CSF	5	16.4 + 3.1	2.2
PEG(10,000)G-CSF (a)	5	68.9 + 10.5	9.3
PEG(10,000)G-CSF (b)	5	95.8 + 6.4	12.9

Both PEG (10,000) G-CSF (a) and (b) have increased the number of neutrophils more than the intact human G-CSF has. Especially, PEG (10,000) G-CSF with a higher extent of the modification showed a more remarkable increase in the number of neutrophils, just like PEG (4,500) G-CSF did.

EXAMPLE 8

Effects of PEG-modified human G-CSF on cyclophosphamide-induced neutropenic mice

Male ICR mice (7 weeks old) were intraperitoneally injected with 200 mg/kg cyclophosphamide (CY) to induce neutropenia. Once a day for successive 4 days starting from one day after the CY injection, PEG (4,500) G-CSF and PEG (10,000) G-CSF as used in EXAMPLE 7 were intravenously injected into the neutropenic mice at a dose of 10 µg protein/kg. At 6, 24 and 48 hrs after the

last injection, blood was collected from orbital vein and neutrophils were counted as in EXAMPLE 5.

As shown in FIG.3, PEG-modified G-CSFs have accelerate the recovery from neutropenia induced by the injection of cyclophosphamide similar or earlier than the intact G-CSF. Especially, PEG (10,000) G-CSF has effected a significant increase in the number of neutrophils.

EXAMPLE 9

Effects of PEG-modified human G-CSF on 5-FU-induced neutropenic mice

Female BDF$_1$ mice (7 weeks old, JAPAN SLC Co.,) were intravenously injected with 200 mg/kg 5-FU to induce neutropenia. At a dose of 10 µg protein/kg once a day for successive 11 days (PEG-1), for every other day (at day 1, 3, 5, 7, 9 and 11; PEG-2) and every third day (at day 1, 4, 7 and 10; PEG-3) starting from one day after the 5-FU injection, the same PEG (10,000) G-CSF as used in EXAMPLE 7 and the intact human G-CSF were subcutaneously injected into the neutropenic mice. At day 7, 8, 9, 10, 11, 12, 14 and 17, blood was collected from orbital vein and neutrophils were counted as in EXAMPLE 5.

As shown in FIG.4, it took about 14 days to recover neutrophil counts of mice injected with only 5-FU to a basal level. On the other hand, it took about 11 days and 9 days to recover neutrophil counts of mice injected also with the intact human G-CSF, and PEG-1, 2 and 3, respectively. Thus, PEG-modified G-CSFs have accelerated the recovery from neutropenia induced by the injection of

5-FU earlier than the intact G-CSF. Moreover, even with fewer times of injection of the PEG-modified G-CSFs than the intact human G-CSF, the same phenomena as the above could be observed.

EXAMPLE 10

Acute toxicity of PEG-modified human G-CSF

Male and female Slc:IR mice (5 weeks old) groups consisting 6 mice each were intravenously administered with the same PEG (4,500) G-CSF and PEG (10,000) G-CSF as used in EXAMPLE 7 as well as vehicles at a dose of 12 ml/kg. General conditions and survival of the treated mice were observed as often as possible for 6 hrs immediately after administration and once a day for the following 14 days. The body weight was checked at the day of injection, 5, 8, 12 and 15th days. Surviving mice were bled to death under ether anesthesia and subjected to pathologic autopsy.

As shown in TABLE 5, no mouse died for the observed period. LD 50 for both PEG (4,500) G-CSF and PEG (10,000) G-CSF was estimated over 3,000 µg protein/kg in both male and female mice. No remarkable change in general condition, body weight or opinion of the autopsy was observed for PEG (4,500) G-CSF or PEG (10,000) G-CSF. These results may suggest that the acute toxicity of PEG-modified human G-CSF is very weak, as the intact human G-CSF is .

TABLE.5 Mortality of male and female mice

Sex	Compound	Dose (μg/kg)	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15 (Day)	Mortality[‡]	LD_{50} (μg/kg)

EXAMPLE 11

Determination of half-life of PEG-modified hG-CSF

Male Sprague-Dawley rats (7 weeks old) were used for study of pharmacokinetics of the intact human G-CSF and PEG (10,000) G-CSF prepared in EXAMPLE 3. Samples were intravenously injected into rats at a dose of 100 µg protein/kg. At 10 min, 2, 4, 8, 24 and 48 hrs after the injection, about 6 -7 ml of blood of each of three rats was collected from abdominal aorta into a polypropylene tube of about 15 ml volume and centrifuged (18,000 x g) at 4°C for 5 min to prepare a serum fraction. An amount of the active human G-CSFs contained in the serum fraction was determined by a bioassay for proliferation induction of mouse bone marrow cells on the basis of incorporation of ^{3}H-thymidine (Ralph et al., Blood 66, pp.633-639, (1988)). The time course of serum concentration is shown in FIG. 5. The results indicate that the half lives of the intact human G-CSF and PEG (10,000) G-CSF are 1.79 hrs and 7.05 hrs, respectively, and AUCs are also 2,000 ng protein hrs/ml and 16,195 ng protein hrs/ ml, respectively. Accordingly, it is demonstrated that the clearance rate of PEG (10,000) G-CSF in the body has been decreased more than that of the intact human G-CSF has.

Industrial Applicability

It is expected that the present PEG-modified human G-CSF may make a great contribution to the treatment with human G-CSF because it has a neutrophils-increasing activity much more lasted than that of the intact human G-

CSF, enabling fewer numbers of administration with a lower dose.
